

Overview of Operating Systems (1)

Dr. Jun Zheng
CSE325 Principles of Operating
Systems
8/21/2019

Major OS Components

- ❑ processes/threads
- ❑ memory
- ❑ I/O
- ❑ secondary storage
- ❑ file systems
- ❑ protection
- ❑ shells (command interpreter, or OS UI)
- ❑ GUI
- ❑ networking

Process management

- ❑ An OS executes many kinds of activities:
 - ❑ users' programs
 - ❑ batch jobs or scripts
 - ❑ system programs
 - ❑ print spoolers, name servers, file servers, network daemons, ...
- ❑ Each of these activities is encapsulated in a **process**
 - ❑ a process includes the execution **context**
 - ❑ PC, registers, VM, OS resources (e.g., open files), etc...
 - ❑ plus the program itself (code and data)
 - ❑ the OS's process module manages these processes
 - ❑ creation, destruction, scheduling, ...

Important: Processes vs. Threads

- ❑ Soon, we will separate the “thread of control” aspect of a process (program counter, call stack) from its other aspects (address space, open files, owner, etc.). And we will allow each {process / address space} to have multiple threads of control.
- ❑ But for now – for simplicity and for historical reasons – consider each {process / address space} to have a single thread of control.

Program/processor/process

- ❑ Note that a program is totally passive
 - ❑ just bytes on a disk that encode instructions to be run
- ❑ A process is an instance of a program being executed by a (real or virtual) processor
 - ❑ at any instant, there may be many processes running copies of the same program (e.g., an editor); each process is separate and (usually) independent
 - ❑ Linux: `ps -auwwx` to list all processes

process A

process B

States of a user process

Process operations

- ❑ The OS provides the following kinds of operations on processes (i.e., the process abstraction interface):
 - ❑ create a process
 - ❑ delete a process
 - ❑ suspend a process
 - ❑ resume a process
 - ❑ clone a process
 - ❑ inter-process communication
 - ❑ inter-process synchronization
 - ❑ create/delete a child process

Memory management

- ❑ The primary memory is the directly accessed storage for the CPU
 - ❑ programs must be resident in memory to execute
 - ❑ memory access is fast
 - ❑ but memory doesn't survive power failures
- ❑ OS must:
 - ❑ allocate memory space for programs
 - ❑ deallocate space when needed by rest of system
 - ❑ maintain mappings from physical to virtual memory
 - ❑ through **page tables**
 - ❑ decide how much memory to allocate to each process
 - ❑ a policy decision
 - ❑ decide when to remove a process from memory
 - ❑ also policy

I/O

- ❑ A big chunk of the OS kernel deals with I/O
 - ❑ hundreds of thousands of lines in Windows, Unix, etc.
- ❑ The OS provides a standard interface between programs (user or system) and devices
 - ❑ file system (disk), sockets (network), frame buffer (video)
- ❑ **Device drivers** are the routines that interact with specific device types
 - ❑ **encapsulates** device-specific knowledge
 - ❑ e.g., how to initialize a device, how to request I/O, how to handle interrupts or errors
 - ❑ examples: SCSI device drivers, Ethernet card drivers, video card drivers, sound card drivers, ...
- ❑ Note: Windows has ~35,000 device drivers!

Secondary storage

- ❑ Secondary storage (disk, FLASH, tape) is persistent memory
 - ❑ often magnetic media, survives power failures
- ❑ Routines that interact with disks are typically at a very low level in the OS
 - ❑ used by many components (file system, VM, ...)
 - ❑ handle scheduling of disk operations, head movement, error handling, and often management of space on disks
- ❑ Usually independent of file system
 - ❑ although there may be cooperation
 - ❑ file system knowledge of device details can help optimize performance
 - ❑ e.g., place related files close together on disk
